HARDFACING ALLOYS

Hardfacing Alloys

Kennametal Stellite is a global provider of solutions to wear, heat, and corrosion problems and is a world-class manufacturer of alloybased materials and components. These consumables come in the form of rod, wire, powder, and electrode and can be custom engineered to meet individual customer needs.

In addition to welding consumables, Kennametal Stellite also offers its expertise and experience in coating services in the form of HVOF (High-Velocity Oxy Fuel) coatings and weld hardfacings. In the UK and in Shanghai, hardfaced components can be manufactured complete to drawing by in-house machine shops.

Industries Served

Kennametal Stellite offers its proven heat, wear, and corrosion experience and customized solutions to a broad range of industries, including:

- Aerospace
- Oil & Gas
- Automotive
- Power Generation
- Steel
- Timber
- Glass
- Forging
- Dental

Hardfacing Alloys

Stellite[™] Alloys

The cobalt-based Stellite[™] alloys are our most wellknown and successful alloys, with the best "all-round" properties. They combine excellent mechanical wear resistance, especially at high temperatures, with very good corrosion resistance. The Stellite[™] alloys are mostly cobalt based with additions of Cr, C, W, and/or Mo. They are resistant to cavitation, corrosion, erosion, abrasion, and galling. The lower carbon alloys are generally recommended for cavitation, sliding wear, or moderate galling. The higher carbon alloys are usually selected for abrasion, severe galling, or lowangle erosion. Stellite[™] 6 is our most popular alloy as it provides a good balance of all of these properties. The Stellite[™] alloys retain their properties at high temperatures where they also have excellent oxidation resistance. They are typically used in the temperature range 315–600° C (600–1112° F). They can be finished to exceptional levels of surface finish with a low coefficient of friction to give good sliding wear.

Deloro[™] Alloys

The Deloro[™] alloys are nickel based with additions of typically Cr, C, B, Fe, and Si. They cover a very wide range of hardness from soft, tough, build-up alloys that are easily machined or hand finished to exceptionally hard, wear-resistant alloys. They can be selected for hardnesses of between 20 and 62 HRC depending on the application. Their low melting point makes these powders ideal for spray/fuse or powder welding applications. The lower hardness Deloro[™] alloys are typically used for glass forming molds. The higher hardness Deloro[™] alloys are used in severe wear applications, such as rebuilding the flights of feeder screws, and they can be blended with carbides for an even harder deposit. They maintain their properties up to temperatures of about 315° C (600° F) and also offer good oxidation resistance.

Tribaloy[™] Alloys

Tribaloy[™] alloys, with either nickel or cobalt base, were developed for applications in which extreme wear is combined with high temperatures and corrosive media. Their high molybdenum content accounts for the excellent dry-running properties of Tribaloy[™] alloys and makes them very suitable for use in adhesive (metal-to-metal) wear situations. Tribaloy[™] alloys can be used up to 800–1000° C (1472–1832° F).

Nistelle[™] Alloys

Nistelle[™] alloys are designed for corrosion resistance rather than wear resistance, particularly in aggressive chemical environments where their high chromium and molybdenum contents provide excellent pitting resistance. As a class, they are also generally resistant to high-temperature oxidation and hot gas corrosion. Care should be taken to select the correct alloy for any given corrosive environment.

Stelcar[™] Alloys

www.kennametal.com/stellite

Stelcar[™] alloys are mixtures of carbide particles and nickel- or cobalt-based powders. Due to their construction, Stelcar[™] materials are available only in powder form, for application by thermal spraying or weld hardfacing.

Selection Table		
	ALLOY	MECHANICAL WEA
	Stellite™	
	Deloro™	
Resistance	Tribaloy™	
Low	Nistelle™	
Satisfactory	Delcrome™	
Very Good	Stelcar™	
Excellent	Jet Kote™	

Jet Kote[™] Powder

Jet KoteTM powders are used for thermal spraying, and they usually consist of either a carbide-metal combination (e.g., WC-Co or Cr_3Cr_2 -NiCr) or a StelliteTM alloy.

Delcrome[™] Alloys

These iron-based alloys were developed to resist abrasive wear at lower temperatures, typically up to 200° C. When compared with our cobalt- and nickel-based alloys, their corrosion resistance is also comparatively low.

TIG and Oxy-Acetylene Welding

In TIG (Tungsten Inert Gas), also known as Gas Tungsten Arc Welding (GTAW), an arc is drawn between a nonconsumable tungsten electrode and the workpiece. The electrode, the arc, and the weld-pool are protected from the atmosphere with an inert shielding gas. The hardfacing material is in the form of a rod. Advantages of the TIG process include simple manual operation and good control of the welding arc. The process can also be mechanised, in which case a manipulator is used to move the workpiece in relation to the welding torch and the hardfacing rod or wire.

Welding rods used for TIG welding are also used for hardfacing with the oxy-acetylene welding process. With the correct operation, a very low level of iron dilution can be achieved in the overlay.

Rod is available in these standard diameters:

- 2,6mm (3/32") (special order)
- 3,2mm (1/8")
- 4,0mm (5/32")
- 5,0mm (3/16")
- 6,4mm (1/4")
- 8,0mm (5/16")

Rod inventory held in North America is typically in 36" lengths. In other countries (also available to special order in the USA and Canada), rod is available in these standard lengths:

- 350mm (14")
- 500mm (20")
- 970-1000mm (38-40" or 3.2-3.3')
- 1,2m (approx. 4' or 47")
- 1,5m (approx. 5' or 60")
- 2m (approx. 6.5')
- 4m (approx. 13')

Rod inventory held in North America is typically packaged in 20 lb bundles. Elsewhere, rod is packaged in 10 kg (22 lb) bundles for the shorter lengths, while longer lengths or larger diameters may be bundled in 25 kg (55 lb) bundles. Rod can also be bundled to customer requirement.

Manual Metal Arc (MMA) Weld Deposition

In this process, an arc is drawn between a coated consumable electrode and the workpiece. The metallic core is melted by the arc and is transferred to the weld pool as molten droplets. The electrode coating also melts to form a gas shield around the arc and the weld pool as well as a slag on the surface of the weld pool, thus protecting the cooling weld-pool from the atmosphere. The slag must be removed after each layer.

MMA welding is still a widely used hardfacing process. Due to the low cost of the equipment, the low operating costs of the process, and the ease of transporting the equipment, this flexible process is ideally suited to repair work.

MIG Weld Deposition, Submerged Arc Welding

In these arc welding processes, consumable hardfacing wire is fed continuously from a spool through the welding torch into the arc, where it is melted and transferred to the workpiece.

In the case of MIG welding, also known as Gas Metal Arc Welding (GMAW), the weld pool is protected from the atmosphere by a stream of shielding gas. The MIG process is very flexible — it can be partially or fully mechanised and is suitable for a wide range of applications.

Wire is also used as the hardfacing consumable in the Submerged Arc Welding (SAW) process. In this process, a mineral-based fluxing powder flows around the consumable wire and is melted by the arc. It forms a gaseous shield around the arc and also forms a slag on top of the weld pool, shielding the cooling weld pool from the atmosphere.

Plasma Transferred Arc (PTA) Weld Deposition

The PTA process is easily automated, providing a high degree of reproducibility of the weld overlays. In addition, because of the highly concentrated heat source, this process benefits from high powder utilization and can achieve a very low level of iron dilution in the overlay.

Because the hardfacing materials are in powder form, it is possible to produce overlays from many different materials and combinations of materials with a wide range of hardness and other properties.

Laser Weld Deposition

When overlaying with a laser, an optical arrangement is used to focus the laser beam on the workpiece and heat it. Simultaneously, hardfacing material in the form of powder or wire is introduced into the laser beam and melted. Due to the narrow heat-affected zone and the fast cooling rate, the heat input is low, thereby producing an almost stress-free overlay.

Compared with other welding processes, for a given hardfacing alloy, the fast cooling rate of the laser process produces an overlay with a significantly higher hardness and finer microstructure.

Depending upon the process parameters and extent of dilution, the hardness of the weld deposit may vary from that provided in the above table.

WM 53–180µm

Plasma Spraying

In the Plasma Spraying process, powder is softened or melted in the plasma gas stream, which also transfers the particles to the workpiece.

The plasma arc is not transferred to the workpiece, it is contained within the plasma torch between an axial electrode and a water-cooled nozzle. The process is operated in normal atmosphere, in a shielding gas stream (e.g., argon), in a vacuum, or under water.

Due to the high temperature of the plasma gas stream, the plasma spray process is especially suitable for spraying high melting-point metals as well as their oxides.

High-Velocity Oxy-Fuel Spray (HVOF)

Spray Nozzle

In the HVOF process, powder is introduced axially into a chamber in which a gas flame is constantly burning under high pressure. The exhaust gas exits through an expansion nozzle which produces a high-velocity gas stream. The powder particles are heated in this gas stream and transferred by it with high kinetic energy to the surface of the workpiece, forming a dense coating with excellent bonding properties.

Due to the moderate transfer of heat to the powder particles and to the workpiece, which remains relatively cool, there is little metallurgical change to the sprayed material and the workpiece.

Flame Spraying with Subsequent Fusing (Spray and Fuse)

Spray and fuse is a two-stage process, the powder alloy being deposited first by flame spraying and then fused. During fusing, the deposit is partially remelted and allowed to resolidify.

In flame-spraying, the powder particles are softened or melted in an oxyacetylene flame and transferred to a prepared workpiece by the expanding gases. An additional gas stream can be used to assist with powder particle transfer.

The second stage of the process, fusing the sprayed coating to the workpiece, is usually done with an oxyacetylene burner. Alternatively, for mass production, fusing can be carried out by induction heating or in a vacuum furnace.

to 0,060" or 0.25 to 1,5 mm) layers, usually on the surface of small cylindrical objects such as pump shafts, packing gland sleeves and pistons, as an alternative to the greater deposit thickness obtained from oxy-acetylene and arc processes. The process can also be used for the facing of flat surfaces, but its possibilities for this type of work are limited.

This process is used for the deposition of relatively thin (0.010"

Since the deposit is thinner and more uniform than that obtained by other welding methods and the heat for fusion is applied uniformly and rapidly, shrinkage and distortion of the component is frequently very small. When the fusing operation is carried out correctly, dilution of the deposit by the base metal is negligible.

Powder Welding

A specially-designed oxy-acetylene torch is used for powder welding. The workpiece is heated with the torch, powder is introduced into the gas stream from the integral powder hopper, and transferred to the workpiece through the flame.

The powder-weld process is ideal for the deposition of smooth, thin, well-bonded layers on flat surfaces on a wide range of substrates, including cast iron. The hardfacing takes place at lower temperatures, which minimizes oxidation and distortion of the workpiece and enables easy surfacing of edges.

						COMPOS	SITE ALLC	YS			
Stelcar [™] Powders Blends of WC, WC/Co and Deloro [™] alloy powders. Size and chemistry to customer requirements								ements			
	Super Stelcar [™] 40	Blenc	l of tungsten	n carbide (40	0%) and Dele	oro 50 [™] alloy	r (60%)				
Super Stelcar [™] 50 Blend of tungsten carbide (50%) and Deloro 50 [™] alloy (50%)											
	Super Stelcar [™] 60	Blend	l of tungsten	n carbide (60)%) and Del	oro 50 [™] alloy	/ (40%)				
	Super Stelcar [™] 70	70 Blend of tungsten carbide (70%) and Deloro 50 ^{°°} alloy (30%)									

Other alloy compositions may be available on request.

¹ Nominal analysis is a guideline only for standard product. Does not include all incidental elements and may differ depending on the exact specification/standard used when ordering. ² Undiluted weld metal. Rockwell (HRC) units unless otherwise stated.

Powder Welding powders are available in these standard size ranges: Spray-fuse powders are available in these standard size ranges:

KS 20–63 μm
 M 45–106 μm (Metco torch)

 • K3
 20-05 μm
 • K
 40-106 μm
 • S
 38-106 μm (Eutectic torch)

K 20–75 μm

Depending upon the process parameters and extent of dilution, the hardness of the weld deposit may vary from that provided in the above table.

PRODUCTIVE ATIVE DANCED

OUR MISSION

Kennametal delivers productivity to customers seeking peak performance in demanding environments by providing innovative customized and standard wear-resistant solutions, enabled through our advanced materials sciences, application knowledge, and commitment to a sustainable environment.

SUSTAINABLE ENGINEERING

With decades of experience, Kennametal offers you some of the most effective opportunities for sustainable manufacturing in the industry using the synergies of superior engineering, leading technology, and tailor-made solutions. Our comprehensive range of products, local support, and excellent customer service make Kennametal your complete supplier of sustainable tooling solutions.

Successful project engineering requires planning, teamwork, and disciplined execution. Through our extensive experience in developing and implementing new project engineering strategies, Kennametal has pioneered a proven methodology to help you manufacture new products and bring them to market quickly. Service deliverables are carefully outlined and jointly agreed to before the project begins. We formally evaluate progress and results with you throughout the project through our stage-gate management system. Kennametal can provide your engineering teams and machine tool builders with process engineering support, advanced metalcutting technologies, and project management expertise to help you achieve your sustainability goals. With our best-in-class process, you'll experience accelerated time-to-market, lower overall costs, and reduced risks to implement new technologies.
